Problems

1. Suppose I (tried to) construct the following circuit in lab, but I find that the LED does not light regardless of how I set the switch. Your task is to help me debug the circuit I constructed by suggesting at least four potential problems I should check for.

![Circuit Diagram]

2. Show how two transistors (and other components) can be used to implement a NAND gate. (Hint: Review the implementations of the NOT and AND gates.)

3. Draw a logic circuit diagram for the following boolean function: \( f = ab + \overline{bc} + (a + c) \)

Optional bonus problem: Show how a NOR gate can be implemented with a single transistor. I encourage you to use outside sources to find a solution to this problem. However, it is not enough to draw the circuit: explain the key insights behind the circuit design, and be sure to cite your sources.
